

NMAO Tournament — Morning Refresher

Written the evening of 2026-08-07 so you can pick this up cold.

The big picture

We're testing the tournament engine end to end for the first time — feeding it a fake round of competitors and watching it do the whole job automatically: sort everyone into fair groups, assign judges, turn judge scores into placements and rating changes, and produce the medal shipping list. “Running a round” means walking that data through the engine's steps, in order, and checking the results look right. The engine lives on Supabase; we trigger each step by calling a small program there called “round-controller.”

What we built today

- **The missing step.** Added the **divide** step — it creates the divisions and pods and seats every competitor. This was the last piece needed to run a full round.
- **A demo round to test with** — 26 fake competitors, 4 schools, 8 judges, arranged to exercise every tricky case.
- **Proof it works** — an automated test runs the engine on the demo data and confirms exactly the right groups (4 divisions, 4 pods). All green.
- **A security fix** — round-controller now has a gate: only an internal caller or signed-in NMAO staff can run it. Deployed via the Supabase command line.
- **Your learning aids** — glossary (plain-language definitions) and run-a-round.md (the full runbook).

Where we are right now

Done: Database verified on the live project (all 11 checks true). Round seeded — its ID is `587dee84-5843-4ecb-a08c-dac5472c386b` (state closed, 26 entries). Function deployed and gated.

Paused on one thing — the key. The function replied “Invalid or expired session,” meaning the key we sent wasn’t recognized as the service-role key. Most likely: Supabase now defaults to a new-style secret key (`sb_secret_...`), but the function checks the **legacy JWT** service-role key (`eyJ...`). We need the legacy one.

Tomorrow — the ordered steps

All in Terminal except step 4 (dashboard SQL). Nothing is destructive; re-running a finished step just does nothing.

1. Open Terminal, go to the project

```
cd ~/Documents/GitHub/NMAO-Tournament
```

2. Set the address + the RIGHT key. Get the **legacy** service_role key: dashboard → Project Settings → API → Legacy API keys → service_role → Reveal/Copy (starts with eyJ...).

```
FN=https://oxzuavpyoetchwebdejp.functions.supabase.co/round-controller
KEY='PASTE_THE_LEGACY_service_role_KEY_HERE'
echo ${KEY:0:10} # want eyJhbGciOi ; if sb_secret_ it's the wrong key
```

3. Run the first two steps — *why*: build the groups, then attach judges.

```
curl -sS -X POST "$FN" -H "Authorization: Bearer $KEY" -H "content-type:
application/json" -d
'{"roundId":"587dee84-5843-4ecb-a08c-dac5472c386b","step":"divide"}'
```

Expect ~ divisions:4, pods:4, assigned:26.

```
curl -sS -X POST "$FN" -H "Authorization: Bearer $KEY" -H "content-type:
application/json" -d
'{"roundId":"587dee84-5843-4ecb-a08c-dac5472c386b","step":"assign_judges"}'
```

Expect ~ 64 judge assignments.

4. Add judge scores — *why*: stand in for judges scoring in the app. In the dashboard SQL Editor, run **seed_demo_scores.sql**. Expect it to report 64.

5. Run the last two steps — *why*: placements + medals.

```
curl ... -d '{"roundId":"587dee84-5843-4ecb-a08c-dac5472c386b","step":"resolve"}'
curl ... -d '{"roundId":"587dee84-5843-4ecb-a08c-dac5472c386b","step":"distribute"}'
```

6. Look at the results. The verification queries are in run-a-round.md (section 3): divisions/pods, placements + rating changes, and medal shipments. Paste any step's output to me and I'll confirm the numbers.

Small reminders

- Keys stay on your machine — never paste the full service-role key into chat (the first few characters are fine when debugging).
- Push today's commits from GitHub Desktop so they're backed up.
- If a step errors, copy the error text to me — each has a specific, fixable cause. We're one key away from the first full round.

Order tomorrow: fix the key → divide → assign_judges → seed_demo_scores.sql → resolve → distribute → look at results.
